## 1 Bayesian Classifiers

According to Bayes Theorem, for a dataset  $x$  with classes  $\omega_i$ , Probability of a datapoint belonging to class  $\omega_i$  is defined as:

$$P(\omega_i|x) = \frac{P(x|\omega_i)P(\omega_i)}{P(x)} \quad (1)$$

- Here,  $P(x|\omega_i)$  is known as the class likelihood.  
To estimate this value, we require the distribution of  $\omega_i$ . Based on the central limit theorem, we can assume that this would be Gaussian distribution for large datasets.
- The value  $P(\omega_i)$  is the class prior and is calculated using:

$$P(\omega_i) = N_i/N \quad (2)$$

This term becomes irrelevant if the classes have equal probabilities.

- $P(x)$  is termed as 'evidence' and can be calculated as:

$$P(x) = \sum_i P(x|\omega_i)P(\omega_i) \quad (3)$$

## 2 Gaussian Likelihood Distribution

For multi-dimensional data, the Gaussian Distribution is:

$$P(x; \mu, \Sigma) = \frac{1}{2\pi^{k/2}|\Sigma|^{1/2}} e^{-(x-\mu)^T \Sigma^{-1} (x-\mu)} \quad (4)$$

where

- $\mu$  is the mean
- $\Sigma$  is the covariance matrix

The above parameters are calculated for the following cases:

- 2.1 Bayes Classifier with Covariance same for all classes**
- 2.2 Bayes Classifier with Covariance different for all classes**
- 2.3 Naive Bayes Classifier with  $C = \Sigma^2 * I$**
- 2.4 Naive Bayes Classifier with C same for all classes**
- 2.5 Naive Bayes Classifier with C different for all classes**

### **3 Bayes Classification**

If  $P(\omega_1|x) > P(\omega_2|x)$  then x belongs to class  $\omega_1$

If  $P(\omega_1|x) < P(\omega_2|x)$  then x belongs to class  $\omega_2$

Using equation (1), this can be written as:

$$P(x|\omega_1)P(\omega_1) \geq P(x|\omega_2)P(\omega_2) \tag{5}$$

This classification rules minimizes number of misclassifications.

## **4 Experiments**

- 4.1 Data**
- 4.2 Parameters**
- 4.3 DET Curves**
- 4.4 Decision Boundaries**
- 4.5 Confusion Matrices**

## **5 Cases**

### **5.1 Subsection Heading Here**

Write your subsection text here.

## **6 Conclusion**

Write your conclusion here.
